

PPT Focus Points

SIH26017 — Predictive Analytics System for Early Detection of Land Acquisition Delays

Our pitch is built around four deliberate focus points. Each one should show up explicitly across the deck — in the framing of the problem, the design of the solution, and the language used to describe it.

1. Ease of Usage for Government Operators

Most end users of this system — district land acquisition officers, revenue department staff — are domain experts, not technologists. The interface has to communicate risk instantly, without requiring any data-science literacy.

What to show in the slides:

- A dashboard screenshot with a single, unmissable risk indicator (color-coded, plain-language) rather than raw scores or technical charts.
- A 'before vs after' framing — manual, paper-based tracking today, versus a one-glance dashboard tomorrow.
- Everyday language throughout: “high risk of delay” instead of “classification probability 0.81”.

Talking points for the video/pitch:

- “An officer with no data background can understand a project's risk in seconds.”
- “We designed this for the person actually using it in the field — not for a data scientist.”

2. Predictions Grounded in Authentic Human Input, Not Just Numbers

Land acquisition is fundamentally about people, not just parcels and paperwork. Our model treats genuine community sentiment — captured through the legally mandated Social Impact Assessment (SIA) and public consultation process — as a first-class signal, not an afterthought bolted onto a numeric model.

What to show in the slides:

- The community sentiment score alongside SIA status as a named, visible input to the model — not hidden inside a black box.
- The human-in-the-loop framing: the AI flags and explains risk; a human official makes the final call. This is a deliberate design choice, worth its own slide.

Talking points for the video/pitch:

- “We don't just crunch acreage and dates — we listen to what the affected community actually says.”
- “Authentic human input, gathered through the legally mandated SIA process, is a core signal in our model — not an afterthought.”
- “The AI recommends; the human decides. This keeps the system accountable for a genuinely high-stakes decision.”

3. The Legalities Concerned

Legal disputes are one of the strongest real-world predictors of delay. The system needs to visibly reflect legal reality — active litigation, stay orders, and dispute type — not treat law as a footnote.

What to show in the slides:

- The “Legal Disputes” pillar as one of the four core risk categories, with its own visible score.
- A worked example: a project with an active stay order, and how the system flags and explains that risk.

Talking points for the video/pitch:

- “Our system doesn't ignore the legal reality of land acquisition — it actively factors in ongoing disputes, stay orders, and litigation type into the risk assessment.”

4. Viability of the Acquisition and the Underlying Project

Not every acquisition carries the same stakes. The system should help officials reason about whether continuing to push a given acquisition is actually justified — tying the risk assessment back to the real-world value and feasibility of the project the land is being acquired for.

What to show in the slides:

- Project-type context alongside risk score — e.g. a highway project vs a mining project may warrant different urgency even at similar risk levels.
- Framing risk scoring as a prioritization tool for resource allocation, not just a delay predictor in isolation.

Talking points for the video/pitch:

- “Beyond just predicting delay, our system helps administrators judge whether continued investment in a given acquisition is the right call given ground realities.”

Quick Reference

Focus Point	Core Slide Idea
1. Ease of Usage	One-glance, plain-language dashboard; before/after comparison
2. Authentic Human Input	SIA + community sentiment as a named model input; human-in-the-loop
3. Legalities Concerned	Legal Disputes pillar; worked stay-order example
4. Acquisition/Project Viability	Project-type context; risk as a prioritization tool
